According the new law for forestry implemented in 2009 new forest management policy was introduced. Increasing ratio of forests have to be treated by continuous forest cover method instead of traditional cut methods. We investigated the biomass available for ungulates in beech forests by strip sample method. We counted the twigs of tree and shrub species and taking into account the mean diameter of the browsed twigs, calculated the biomass. We stated that even after some years after change to continuous forest cover management the food supply available for ruminants was increased.
